

Text A:

As many organisations continue to propose new use cases for contemporary technologies, researchers have sought to understand what role these technologies play within an organisational context. Especially, artificial intelligence (AI) has attracted the attention of many scholars. A wide range of literature predicts that AI will shape the future of the economy. As its applications further evolve within the domain of non-routine cognitive tasks, many researchers agree that this technology will change the nature of work and demand new expertise (Frey and Osborne, 2017; Faraj et al., 2018; Brynjolfsson et al., 2018; Barley et al., 2017). This trend is also applicable in the medical sector, which is predominantly interested in two application areas: First, natural language processing transforms unstructured data, such as clinical notes, into a more structured format. Second, the analysis of structured data has the potential to facilitate the diagnosis process (Jiang et al., 2017).

Text B:

While mediatisation establishes the broader conditions under which the media operates, alone it does not fully account for the power of media narratives and discourses, or how they are constructed, interpreted, or enacted on a wider scale. The mediatisation literature incorporates some aspects of the media-public feedback loop (e.g. media realities, selectivity, newsworthiness) but is limited to the contextual specificity of the overall process. The media-public relationship is a key concern: in order to strengthen its political influence and impetus, the media must shape public engagement with particular narratives. Three mechanisms are central to this process: ‘the what’, which stories become newsworthy (*agenda-setting*); ‘the how’, the means by which the boundaries of legitimate discourse are set (*framing*), and; finally, ‘the why and for whom’ this is done, be it commercialism, media logic, or other forces (*manufacturing consent*). By examining these theories in detail, a further dimension of the media’s role, via the public, sheds light on how HE leaders respond to media discourses.

Text C:

The impact of computerisation on labour market outcomes is well-established in the literature, documenting the decline of employment in routine intensive occupations – i.e. occupations mainly consisting of tasks following well-defined procedures that can easily be performed by sophisticated algorithms. For example, studies by Charles et al. (2013) and Jaimovich and Siu (2012) emphasise that the ongoing decline in manufacturing employment and the disappearance of other routine jobs is causing the current low rates of employment. In addition to the computerisation of routine manufacturing tasks, Autor and Dorn (2013) document a structural shift in the labour market, with workers reallocating their labour supply from middle-income manufacturing to low-income service occupations. Arguably, this is because the manual tasks of service occupations are less susceptible to computerisation, as they require a higher degree of flexibility and physical adaptability (Autor et al., 2003; Goos and Manning, 2007; Autor and Dorn, 2013).
